

JERZY BUTRYM (LUBLIN), WITOLD ZUCHIEWICZ (KRAKÓW)

ON NEW SITES OF SOLIFLUCTION AND DELUVIAL (WASHOUT) DEPOSITS IN THE ROŻNÓW FOOTHILLS, OUTER WEST CARPATHIANS

INTRODUCTION

The paper deals with Quaternary slope deposits occurring in the Rożnów Foothills, Outer West Carpathians (Fig. 1). Special attention has been given to critical evaluation of the results of thermoluminescent datings.

STATE OF KNOWLEDGE

Quaternary deposits covering floors and sides of valleys of the Dunajec river and its tributaries have been studied by Uhlig (1888), Szajnocha (1902), Sokolowski (1935), Klimaszewski (1937, 1948, 1961, 1967), Kozikowski (1953), and Starkel (1972, 1988). In the last decade, detailed geomorphic and geological studies were carried out by Zuchiewicz (1983, 1984), who dealt mainly with Quaternary fluvial covers and the development of river terraces. Aeolian and washout deposits in southern part of the Rożnów Foothills were described by Butrym and Zuchiewicz (1985, in print) and Butrym et al. (in print), whereas results of malacological studies of loess-like covers were presented by Aleksandrowicz and Zuchiewicz (1988, in print).

GEOLOGIC AND GEOMORPHIC SETTING

The area under study (Fig. 1) belongs to the Rożnów Foothills, developed on rocks that compose the Silesian, Grybów (Dukla s.l.), and Magura thrust sheets, built up from flysch complexes of differentiated age (Cretaceous through Oligocene) and resistance to erosion.

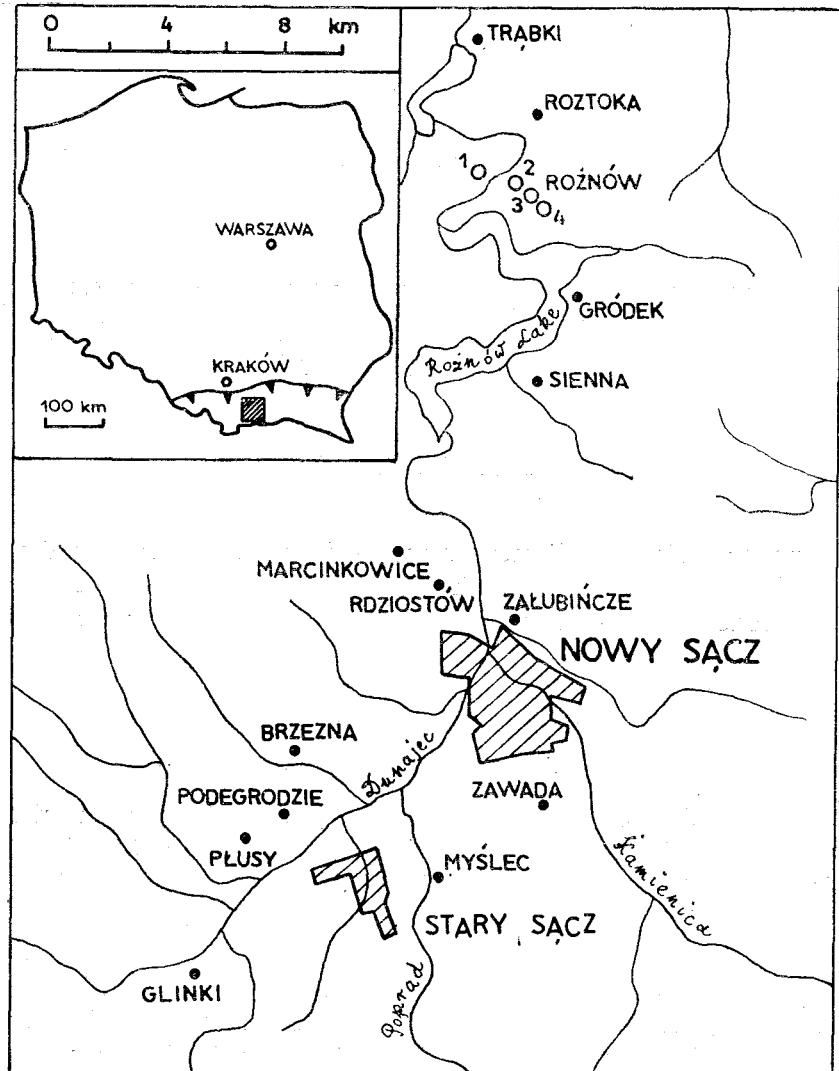

Fig. 1. Localization sketch showing place names mentioned in the text. 1—4: sites of solifluction-deluvial deposits of the Rożnów area, dated by the TL method at: 1 — 42 ± 6 ka BP (Lub-819), 2 — 60 ± 9 ka BP (Lub-818), 3 — 71 ± 10 ka BP (Lub-817), 4 — 51 ± 7 ka BP (Lub-816)

Ryc. 1. Szkic lokalizacyjny. 1—4: stanowiska osadów soliflukcyjno-deluwialnych w rejonie Rożnowa, datowanych metodą TL: 1 — 42 ± 6 ka BP (Lub-819), 2 — 60 ± 9 ka BP (Lub-818), 3 — 71 ± 10 ka BP (Lub-817), 4 — 51 ± 7 ka BP (Lub-816)

The region in question is composed of a number of ridges (400—450 m a.s.l.) separated by valleys of the Dunajec river and its tributaries, attaining up to 250 m in depth. The valley sides bear flights of rock-cut, erosion-accumulation and cut-and-fill terraces formed, as re-

cently supposed (B u t r y m, Z u c h i e w i c z in print), during the Otwock, Narew, Nida, San, Odra, Warta, Vistula, and Holocene stages. Most of these terraces is overlain by solifluction, washout and/or loess-like deposits. The convex-concave slopes of interfluve ridges are modelled by numerous landslides, landslumps and landslips, some of them showing manifestations of recent activity.

SOLIFLUCTION-DELUVIAL (WASHOUT) DEPOSITS

These covers are widespread throughout the Rożnów Foothills, occurring at talus feet and within dellen. Their thickness ranges from 2—3 to 5—8 m.

Solifluction covers, 2—6 m thick, overlie and/or intertwine with alluvia of terraces formed during glacial stages. These are sandy, sand-clayey, and sand-silty loams, clays and sandy silts, containing fragments of disintegrated shales and/or flat, angular sandstone scraps, 2—5 to 8—15 (20—30) cm in diameter, aligned parallel to the slope surface. They occur within near-slope parts of fluvial covers, as-

Ryc. 3. Szkic topograficzny rejonu Rożnowa

sociated with the Narewian, Nidianian, Sanian, Odranian, Wartanian, and Vistulian stages.

The oldest TL-dated solifluction loams comprise deposits occurring on top of a gravel series of the South-Polish terrace at Gródek (Figs. 2, 4). These deposits date back to the Odra glacial stage. Solifluction covers are best exposed at Rożnów, overlying a gravel series of the Odranian terrace (Figs. 3, 5). The section discloses a 2—3 m thick solifluction deposits, overlying 2—4 m thick gravels of the Dunajec river terrace, resting on a 16—18 m high rock socle, built up from the Godula beds (Fig. 4, section D). The gravel series is here overlain by (from the bottom upwards):

- 0.00—0.60 m very fine-grained sands with angular sandstone debris, 2 cm in diameter
- 0.60—0.86 very fine to fine-grained, light-brown sands with a subordinate amount of angular debris of the Godula sandstones, 0.4—1.5 (3) cm in diameter
- 0.86—1.06 dark-yellow, fine-grained sands bearing infrequent sandstone debris, ϕ 0.5—4 cm, and small shale fragments, 0.5—1.5 cm in diameter

1.06—1.20 m	dark-yellow fine-grained sands, TL-dated at 60 ± 9 ka BP (Lub-818)
1.20—1.64	poorly cemented, dark-yellow fine-grained sands with angular sandstone fragments, ϕ 0.2—1 to 3—6 cm, and shale clasts, ϕ 0.5—2 cm, aligned parallel to the slope surface
1.64—1.70	grey and yellow silty loams, cemented, rusty at places, non-calcareous, bearing isolated, 4—5 cm in diameter, well-rounded and moderately weathered granitic pebbles, mixed with angular debris, ϕ 0.3—3 cm
1.70—1.90	grey, yellow and rusty when weathered, silty loams with shale fragments, 2—5 cm in diameter, and fine sandstone debris, ϕ 0.3—1 to 2—6 cm, aligned parallel to the slope surface
1.90—2.20	dark-yellow silt-sandy loams.

On the right side of the Dunajec valley at Roźnów-Radajowice (Fig. 6, section A), there crop out solifluction deposits that mantle a gentle slope, surrounding the erosion-accumulational Odranian terrace:

0.00—0.50 m	fine angular sandstone debris, 0.5—2 cm in diameter, interspersed within dark-brown sandy loams
0.50—0.85	light-bluish, fine-grained sands bearing infrequent fragments of the Godula sandstones, ϕ 0.2—0.5 to 2—5 cm, aligned parallel to the slope surface. Sands are poorly cemented by CaCO_3 and show numerous plant intergrowths
0.85—1.05	carbonate-cemented, fine-grained and silty sands, containing numerous sandstone fragments, 1—6 cm in diameter, averaging at 4 cm, aligned parallel to each other
1.05—1.30	light-brown sandy loams bearing infrequent sandstone fragments, ϕ 2—4 cm, some of them being partly rounded
1.30—1.35	light-brown, fine-grained and silty sands bearing infrequent, parallel oriented, sandstone debris, 1—4 cm in diameter
1.35—1.50	brown sandy loams, containing fine angular debris, ϕ 0.5—3 cm, aligned parallel to the slope surface.

TL ages of solifluction loams at Roźnów point to the older pleniglacial of the last cold stage (Lub-816: 51 ± 7 ka BP, Lub-818 60 ± 9 ka BP). These deposits occur, most frequently, on slopes built up from poorly resistant shale and shale-sandstone flysch complexes.

Washout (degluvial) deposits mantle talus feet and encroach upon river terraces, their thickness ranging from 5 to 8 m.

The 2—4 m thick gravel series of the South-Polish stage at Gródek, occurring at an altitude of 298 m a.s.l. (26 m above the Roźnów Lake

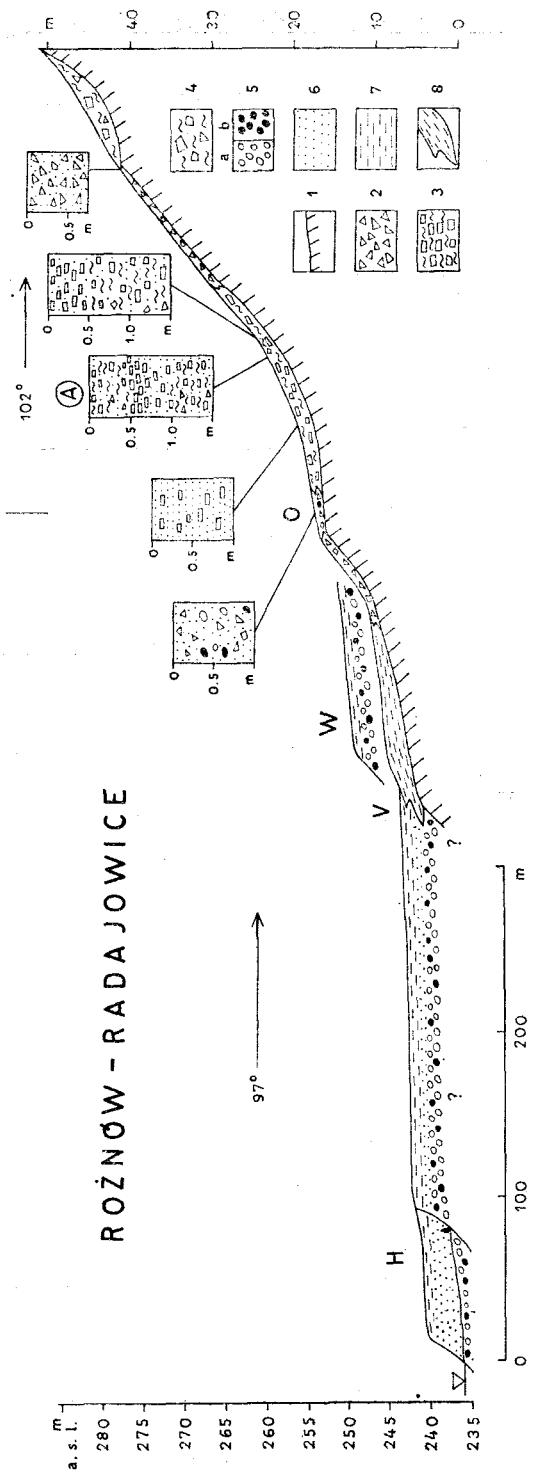

Fig. 6. Section across the right Dunajec valley side at Roźnów-Radajowice (cf. Fig. 3, G-H). 1 — rock socle, 2 — angular rock debris, 3 — solifluction cover, 4 — landslide colluvia, 5 — fluvial gravels (a — flysch-derived, b — Tatra-derived), 6 — sands, 7 — muds, 8 — alluvial fan deposits. Symbole literowe — piętra: O — Odra, W — Warta, V — Wisła, H — holocen

average level), is covered by solifluction-washout deposits, attaining 5 m in thickness (Figs. 2, 4):

- 0.00—1.20 m series composed of well to moderately rounded pebbles, densely packed and strongly limonitized. Their petrographic inventory includes the Magura, Ciężkowice and Krosno sandstones, alongside with strongly weathered, Tatra-derived granites and very well rounded and well-preserved Werfenian quartzites. Pebbles derived from flysch complexes are very poorly rounded, flat and discoidal; they reveal poorly developed imbrication and poor sorting measures. The pebbles are 5—10 to 15—16 cm in diameter and rest within fine gravel, ϕ 1—2 cm, and coarse- to medium-grained sands, being mixed with fine weathered granitic debris
- 1.20—1.21 Fe-Mn hardpan
- 1.21—1.25 light-yellow, very fine-grained and silty sands, dated by the TL method at 267 ± 40 ka BP (Lub-1026)
- 1.25—1.27 sands as above, strongly ferruginous
- 1.27—1.33 grey sandy muds, rusty when weathered, bearing plant intergrowths
- 1.33—1.35 ferruginous sandy muds
- 1.35—1.60 light-grey sandy muds
- 1.60—2.60 silt-sandy loams with infrequent intercalations of fine- to medium-grained sands and fine, angular sandstone and quartz debris, 0.5 to 1.5 cm in diameter.
TL dates: 2.25 m Lub-1022 297 ± 44 ka BP
2.50 m Lub-1023 103 ± 15 ka BP
- 2.60—3.20 coarse- to medium-grained sands with isolated quartz grains, ϕ 0.2—1 cm, derived from the Ciężkowice sandstones exposed higher upslope
- 3.20—4.70 sand-silty, cemented loess-like deposits, TL dated at:
3.20 m Lub-1024 89 ± 13 ka BP
3.75 m Lub-1025 61 ± 9 ka BP.

A peculiar TL-date inversion, found in the lower part of the section, may result from a too short downslope transport route of the clastic material.

On the left side of the Dunajec river valley at Roźnów, shortly north of the water-dam (Fig. 1), there occurs a 16 m high bench situated beneath a landslide slope, covered by 3.5 m thick deluvia. These are light-brown sandy loams, underlain by angular debris of the Istebna sandstones. Higher upslope (250 m a.s.l., 26 m above the Dunajec river bed), these loams pass gradually into grey, yellow-rusty when weathered, cemented sandy silts, dated at 42 ± 6 ka BP (Lub-819).

South of the meander hill at Roźnów (Fig. 1), at the outlet of a small

gully, the following section of washout deposits (290 m a.s.l.) has been found (from the bottom upwards):

0.0—2.5 m	regolith cover composed of loams and sandstone debris, overlying exposures of the Godula beds
2.5—3.0	light-brown, very fine-grained sands, bearing infrequent angular debris, 3—5 cm in diameter
3.0—4.3	light-brown sandy loams
4.3—4.9	very fine-grained sands, horizontally laminated, grey, yellow and rusty when weathered, muscovitic. Some of laminae strongly cemented with limonite. Numerous carbonate concretions, 1—4 cm in diameter, also visible. TL date: 71 ± 10 ka BP (Lub-817)
4.9—6.3	sands as above, strongly limonitized
6.3—8.0	light-yellow, very fine-grained and silty sands.

Lower parts of valley sides of gullies dissecting the left side of the Wiesiółka stream valley at Roźnów, are mantled by 3—4 m thick, light-grey sands and sandy silts, dated at the bottom at 51 ± 7 ka BP (Lub-816), and covered by 0.5—1 m thick layer of dark-yellow sandy loams.

The described washout deposits occur either on top of solifluction loams (Figs. 4, 5) or overlie fluvial series (Fig. 7). At some places, they also over- and underlie loess-like sediments. Deluvial covers are represented by vari-grained sands, silty sands, sandy and sand-silty loams, as well as sandy silts (Figs. 8, 9). These deposits are usually poorly sorted and contain a relatively small amount of silt (12—16%).

AGE IMPLICATIONS

Washout covers mantle fluvial deposits laid down during the Narewian (Trąbki), Sanian (Gródek), Odranian (Roźnów), Wartanian (Roztoka), and Vistulian (Sienna) stages. In the light of thermoluminescent datings, deluvia occurring on top of older gravel series are usually Early Vistulian in age (Gródek), and may be correlated with the lowest and lower younger loess horizons (M a r u s z c z a k 1980, 1985). Washout deposits of the Roźnów area (Fig. 10), in turn, are older Vistulian pleniglacial in age and may refer to the lower younger loess horizon. Interpleniglacial age, however, is characteristic for deluvial covers that overlie solifluction series at Roźnów-Roztoka (cf. A l e x a n d r o w i c z, Z u c h i e w i c z in print), whereas sandy loams occurring immediately above the Sanian gravels at Marcinkowice (Fig. 10, cf. also B u t r y m, Z u c h i e w i c z, in print), seem to represent the Wartanian.

CONCLUDING REMARKS

TL age determinations of solifluction and deluvial deposits do not provide convincing results. In most cases, TL ages seem to be considerably older than those expected from geologic and geomorphic analyses of deluvial covers. The latter refer, most probably, to the late pleniglacial times of the last cold stage (Vistulian), as do loess-like deposits at Sienna and Roztoka (Butrym *et al.*, in print; Butrym, Zuchiewicz, in print; Aleksandrowicz, Zuchiewicz 1988, in print). As far as solifluction covers are concerned, the short transport of the clastic material down the slope makes proper TL determination difficult. We are of the opinion that further detailed studies, including palynological and magnetostratigraphic ones, are required to obtain more reliable results.

Nowe stanowiska utworów soliflukcyjno-deluwialnych na Pogórzu Rożnowskim w Zewnętrznych Karpatach Zachodnich

Artykuł omawia szereg nowych stanowisk utworów soliflukcyjno-deluwialnych występujących na obszarze Pogórza Rożnowskiego u podnóża stoków oraz wkraczających na terasy rzeczne lub zazębiających się z różnowiekowymi aluwiami terasowymi doliny Dunajca. Niektóre z tych utworów były datowane metodą termoluminescencji. Uzyskane daty (piętro Odry — starszy pleniglacjał piętra Wisły) budzą jednakże szereg wątpliwości.

РЕЗЮМЕ

Е. Бутрым, В. Зухевич

НОВЫЕ МЕСТОНАХОЖДЕНИЯ СОЛИФЛЮКЦИОННО-ДЕЛЮВИАЛЬНЫХ ОБРАЗОВАНИЙ НА РОЖНОВСКОМ ПРЕДГОРЬЕ ВО ВНЕШНИХ ЗАПАДНЫХ КАРПАТАХ

В статье рассматривается ряд новых местонахождений солифлюкционно-делювиальных образований, выступающих на территории Рожновского предгорья у подошвы склонов и распространяющихся на речные террасы или же соприкасающихся с разновозрастными террасообразными аллювиями долины р. Дунаец. Некоторые из этих образований датировались по методу термолюминесценции. Полученные даты (ярус Одры — старший плениглациал яруса Вислы) вызывают, однако, ряд сомнений.
